Hypothesis Report | **Case Study:** Circles.Life Singapore

Introduction:

This report presents four data-informed CRO hypotheses for the Circles.Life Singapore homepage and plan-selection funnel. Each hypothesis follows structured framework, includes the observed friction point, the proposed change, the primary success metric, and a recommended test methodology. Hypotheses span UX clarity, pricing psychology, trust signals, and mobile-funnel friction — the four highest-impact levers for a digital-first telco.

Hypothesis 1: Clarify the Hero Section CTA to Reduce Above-the-Fold Bounce

UX/Content

Hypothesis:

- Replacing the abstract hero tagline with a price-anchored, benefit-led headline removes the cognitive effort required for a first-time visitor to self-qualify.
- Redirecting 'Get Started' and 'Explore Plans' away from on-page anchors to a dedicated plan or checkout page intercepts high-intent micro-moments before re-evaluation friction sets in.

Rationale:

- When the headline immediately answers "what do I get and what does it cost," visitors arrive at the CTA already pre-convinced — lifting hero CTR and compressing time-to-first-click. A benefit-first headline reduces cognitive load and aligns with search intent.
- A user clicking a primary CTA has already signalled action intent — dropping them back into the same page resets their decision loop. Routing them forward in the funnel converts that intent into progression, improving CTA-to-checkout entry rate.

Testing:

- A/B test (50/50 split) via VWO or Optimizely. Minimum sample: ~5,000 unique visitors per variant. Run for 2–3 weeks.
- Track: hero CTR, scroll depth, and plan-page entry rate as guardrail metrics.
  - Primary metric: Hero CTA Click-through Rate (CTR)
  - Secondary metrics: Scroll depth past hero, bounce rate, time on page

Hypothesis 2: Reduce Plan-Selection Confusion with a Smart Recommender Prompt & Personalization

UX/Funnel/AOV

Hypothesis:

- Introducing a 3-question "Help Me Choose" micro-quiz above the plan cards can simplify decision-making by matching users with the most relevant plan based on usage intent, roaming needs, and budget sensitivity.
- This reduces cognitive overload during plan comparison, strengthens purchase confidence, and creates a more guided conversion journey — particularly for mobile users navigating multiple plan options.

Rationale:

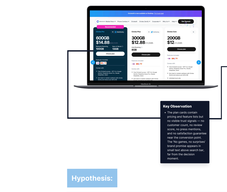
- The Paradox of Choice (Schwartz) is well-documented in subscription products. Telco plan comparison is inherently confusing — GB counts, roaming zones, and price tiers require effort to decode. A lightweight recommender shifts the mental burden from the user and communicates product knowledge.
- Personalised plan recommendations reduce choice overload by narrowing decision pathways and aligning users with plans that match their usage intent and price sensitivity. A guided recommendation flow also creates strategic upsell opportunities by surfacing higher-value plans within the user's accessible budget range — increasing purchase confidence, improving plan-to-checkout conversion, and potentially lifting overall AOV.

Testing:

- A/B test: Control (existing plan grid) vs Variant (plan grid with quiz prompt banner above cards). Track quiz completion rate as a secondary engagement signal. Use Hotjar/MS Clarity session recordings to observe interaction patterns in both variants.
- Track: Choose Plan CTR, Quiz engagement as guardrail metrics.
  - Primary metric: Plan card → 'Choose Plan' CTA click-through rate
  - Secondary metrics: Quiz completion rate, plan page exit rate, checkout initiation rate

Hypothesis 3: Add Social Proof & Trust Signals Near the Plan CTAs

CREDIBILITY



Hypothesis:

- Adding a trust bar directly below the plan cards can reinforce credibility at the highest-intent stage of the funnel by surfacing social proof, reliability signals, and risk-reduction cues near the conversion CTA.
- Trust indicators such as customer adoption, network reliability, ratings, and satisfaction guarantees help reduce hesitation for users comparing Circles.Life against established telecom incumbents, increasing purchase confidence and improving plan-selection conversion rates.

Rationale:

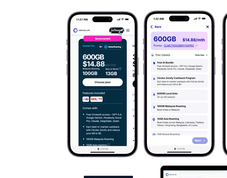
- Industry studies from BrightLocal and Nielsen consistently show that embedded social proof within purchase journeys can meaningfully improve conversion rates in subscription-led businesses. For a challenger telco like Circles.Life, trust reinforcement becomes important, as users are committing to an ongoing service relationship with a comparatively less established brand versus incumbents such as Singtel or StarHub.
- Positioning credibility signals directly near the plan-selection CTA helps reduce perceived switching risk, validates service reliability, and increases confidence at the final decision stage.

Testing:

- A/B test. Control: existing plan cards. Variant: trust bar added below cards. Segment analysis by new vs returning visitors (trust signals typically have stronger effect on new users). Run for minimum 3 weeks to track new and returning user behaviour.
- Track: Choose Plan CTR, return customer rate as guardrail metrics.
  - Primary metric: Plan card → Choose Plan' CTA conversion rate (plan page)
  - Secondary metrics: Scroll-to-CTA rate, return visit rate/repeat customer rate

Hypothesis 4: Optimise Bottom-Funnel Checkout Flow to Reduce High-Intent User Leakage

CHECKOUT/ FUNNEL



Hypothesis:

- Introducing a visible checkout progress indicator, reducing the initial form to essential fields only, and enabling Google/Apple sign-in can lower perceived effort during mobile checkout entry.
- Simplifying the early-stage checkout experience reduces friction across address and payment stages, strengthens progression momentum, and improves completion rates among high-intent users already deep in the funnel. Offering familiar authentication methods lowers the activation barrier at the highest-dropout step of the funnel.

Rationale:

- Despite offering express checkout, the current mobile flow still requires multiple interactions, extended scrolling, and repeated input effort across detail, address, and payment stages.
- These bottom-funnel users represent the highest conversion-value audience, making leakage at this stage especially costly. Reducing friction, shortening perceived checkout length, and improving action continuity can help preserve purchase intent and minimise abandonment at critical conversion touchpoints.

Testing:

- Multivariate test on mobile traffic only (segment by device). Test three elements: (a) progress bar, (b) social login, (c) reduced initial fields — either independently or as a combined 'optimised flow' variant vs control. Use funnel analysis to identify the exact step with highest drop-off before and after the change.
- Track: Checkout completion rate, checkout abandonment rate as guardrail metrics.
  - Primary metric: Mobile checkout completion rate (from plan select to order confirmed)
  - Secondary metrics: Form abandonment rate by step, avg time to complete checkout, mobile bounce rate post-CTA

Observations / Summary / Recommendations:

The website currently presents multiple UX and conversion inefficiencies across navigation, interaction design, and content hierarchy. The navigation bar contains too many offerings and secondary services, diluting focus from the core telecom conversion journey and increasing cognitive overload. Recommended plans appear inconsistent across pages, while hover-based interactions and gamified elements create unnecessary distraction without adding functional value — particularly on mobile. Key monetization opportunities such as Cinch collaborations, device bundling, and value-added benefits remain hidden deep in the bottom funnel instead of being surfaced earlier near decision-making touchpoints. Trust-enhancing benefits like free caller ID, no-transfer fees, and network reliability are also under-leveraged near critical CTAs. Additionally, low-value content section such as "We Are Social" and "Rest of World" occupy valuable screen space that could be reallocated toward conversion-focused messaging, plan comparisons, or trust reinforcement. Additionally, certain content labels and messaging structures create unnecessary ambiguity within the user journey. For example, reframing "We Are Social" to "We're on Social" and replacing "Rest of World" with clearer country applicability messaging would improve comprehension and contextual clarity. More intuitive, value-driven, SEO-led content framing can reduce user confusion, strengthen information hierarchy, and create a more conversion-oriented experience aligned with purchase intent.

CRO & Performance Summary:

From a CRO perspective, the broader experience suffers from weak interaction performance, including loading delays, page refresh issues, lock states, broken pages, and inconsistent responsiveness — all of which negatively impact perceived reliability and purchase confidence. Usability is further affected by excessive scrolling, sticky navigation support, and fragmented action continuity across the funnel. Optimising page speed, responsiveness, simplifying navigation architecture, reducing non-essential interaction elements & gamification, and improving content prioritisation and strategic redirection can create a more focused, performance-driven user journey from discovery to checkout. Overall, the highest opportunity lies in reducing friction, improving trust visibility, and strengthening value communication at key conversion touchpoints throughout the funnel.

Thank you for the opportunity — I'm excited about the possibility of driving measurable growth for AnalyticsLiv's clients. Happy to walk through any of these hypotheses in more depth during the next round.
